An optimized SINE strategy for multiplexing non-overlapping single nucleotide polymorphism genotyping. Simultaneous multiplex genotyping of non-overlapping single nucleotide polymorphisms (SNPs) is becoming increasingly important, especially for the detection of large numbers of SNPs in genome-wide association studies. We have developed a new, highly sensitive and cost-effective approach for SNP genotyping. We describe here a multiplex assay that simultaneously genotypes non-overlapping SNPs using a single set of SINE (single nucleotide extension)-based primers. SINE-based primers are initially designed for each SNP to amplify either allele 1 or allele 2. SINE primers used to amplify the non-allelic SNPs will undergo SINE-PCR. Using SINE primers to amplify a non-allelic SNP will result in a detectable fragment, whereas amplification using allele-specific SINE primers will not result in a detectable fragment. Four different sets of non-allelic primers were tested, resulting in a high average sensitivity of SNP detection and a low false-positive rate. The multiplex assay was optimized for ABI PRISM 310 Genetic Analyzer. A total of 10 microliters of reaction mixture, containing 5 pmol primer, was sufficient to detect less than 0.05% of the heterozygotes at the locus. No cross-amplification of non-target loci was observed. In conclusion, the method allows the simultaneous genotyping of up to 60 SNPs without multiplex PCR, with high specificity and sensitivity./* * Copyright 2012-2020 The Pkcs11Interop Project * * Licensed under the Apache License, Version 2.0 (the "License"); * you may not use this file except in compliance with the License. * You may obtain a copy of the License at * *
